PROJECT REPORT

Respiratory Disease Risk Prediction System

Introduction

Respiratory diseases such as Chronic Obstructive Pulmonary Disease (COPD), pneumonia, asthma, and bronchitis are among the leading causes of global health issues. Early detection of such diseases is crucial for effective treatment and prevention.

With the advancement of Artificial Intelligence and Machine Learning, it has become possible to predict diseases using non-invasive techniques like respiratory sound analysis. This project presents a system that predicts respiratory diseases using machine learning and deep learning techniques based on input data such as respiratory sounds or health parameters.

The system aims to assist healthcare professionals by providing early-stage predictions and improving diagnostic efficiency.

Objective

The main objectives of this project are:

- To develop a machine learning-based system for predicting respiratory diseases
- To analyze respiratory data (such as breathing sounds or patient features)
- To classify diseases into categories like COPD, Pneumonia, Bronchitis, etc.
- To provide an easy-to-use interface for users to input data and get predictions

3. Methodology

The system follows a structured machine learning pipeline**:**

Step 1: Data Collection

- Dataset contains respiratory sounds or patient-related attributes
- Includes multiple disease classes and healthy samples
- Real-world datasets often include recordings from multiple patients across age groups

Step 2: Data Preprocessing

- Cleaning and formatting the dataset
- Handling missing values

- Feature extraction (e.g., MFCC for audio signals)
- Normalization of data

Step 3: Feature Extraction

- Important features are extracted from raw data
- In audio-based systems, MFCC (Mel-Frequency Cepstral Coefficients) are commonly used

Step 4: Model Training

- Machine learning / deep learning models are used
- Common models:
    - CNN (Convolutional Neural Network)
    - GRU / RNN (for sequential audio data)
- The model learns patterns from training data

Step 5: Prediction

- User inputs new data (audio or parameters)
- Model predicts disease category

Technologies Used

- **Programming Language:** Python
- **Libraries:**
    - NumPy
    - Pandas
    - Librosa (audio processing)
    - TensorFlow / Keras
- **Framework:** Flask (for web app)
- **Frontend:** HTML, CSS, JavaScript

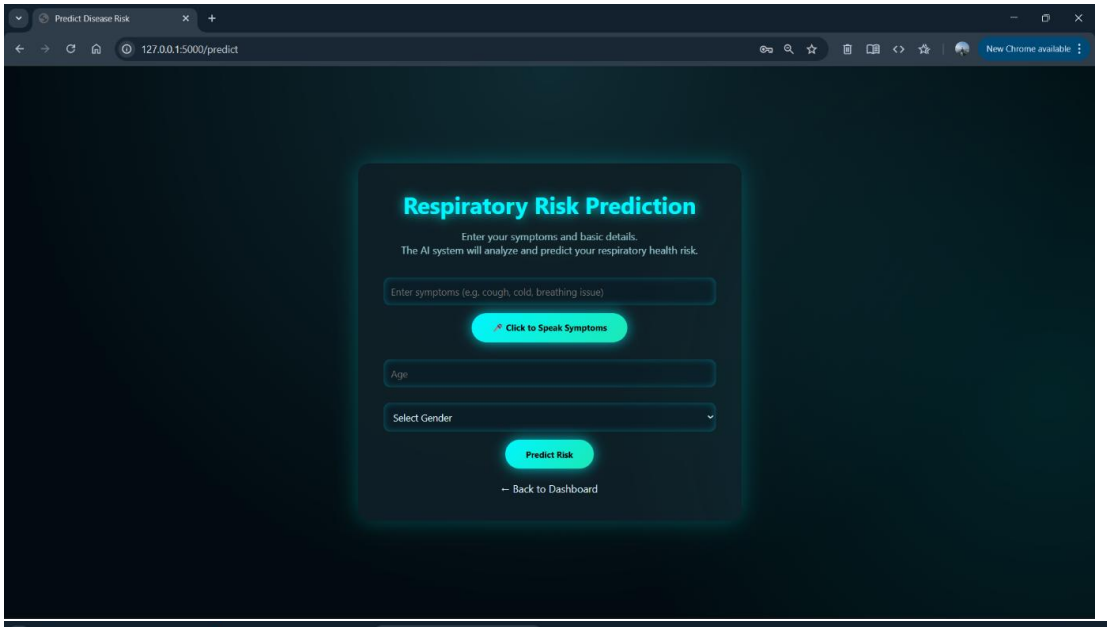
Dataset Used: Patient Chronic Dataset.CSV

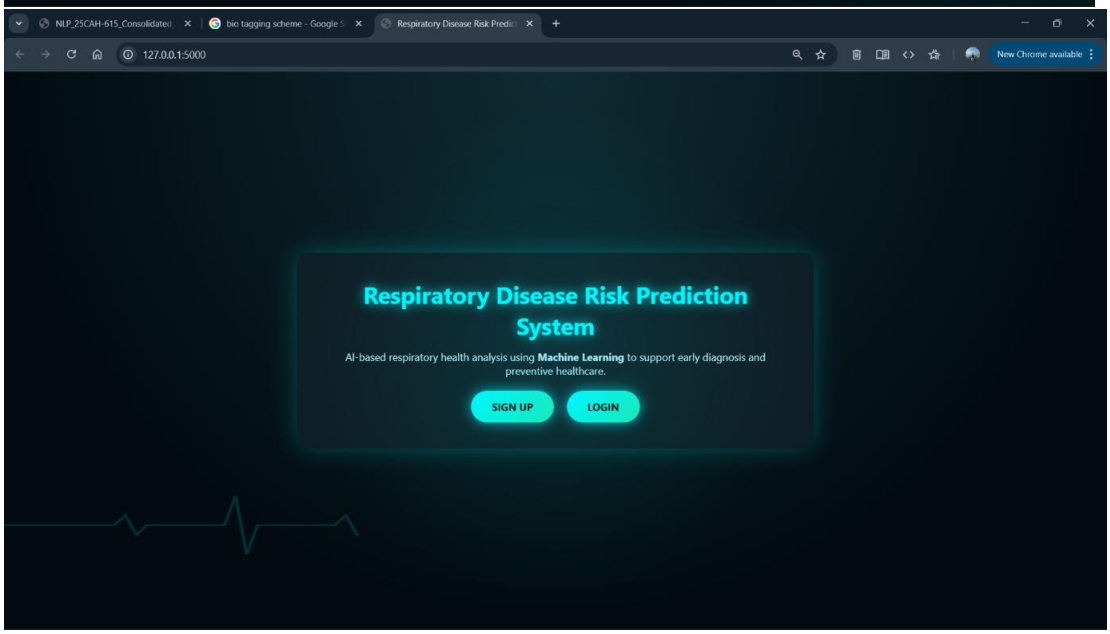
System Architecture

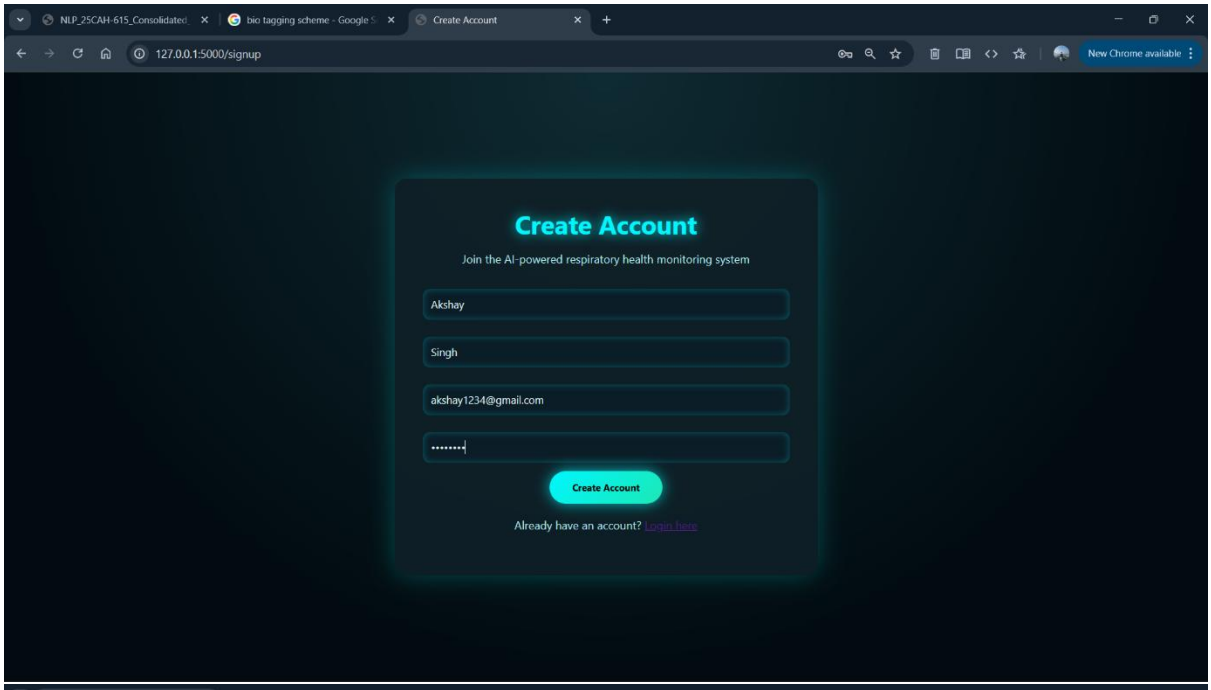
The system consists of the following components:

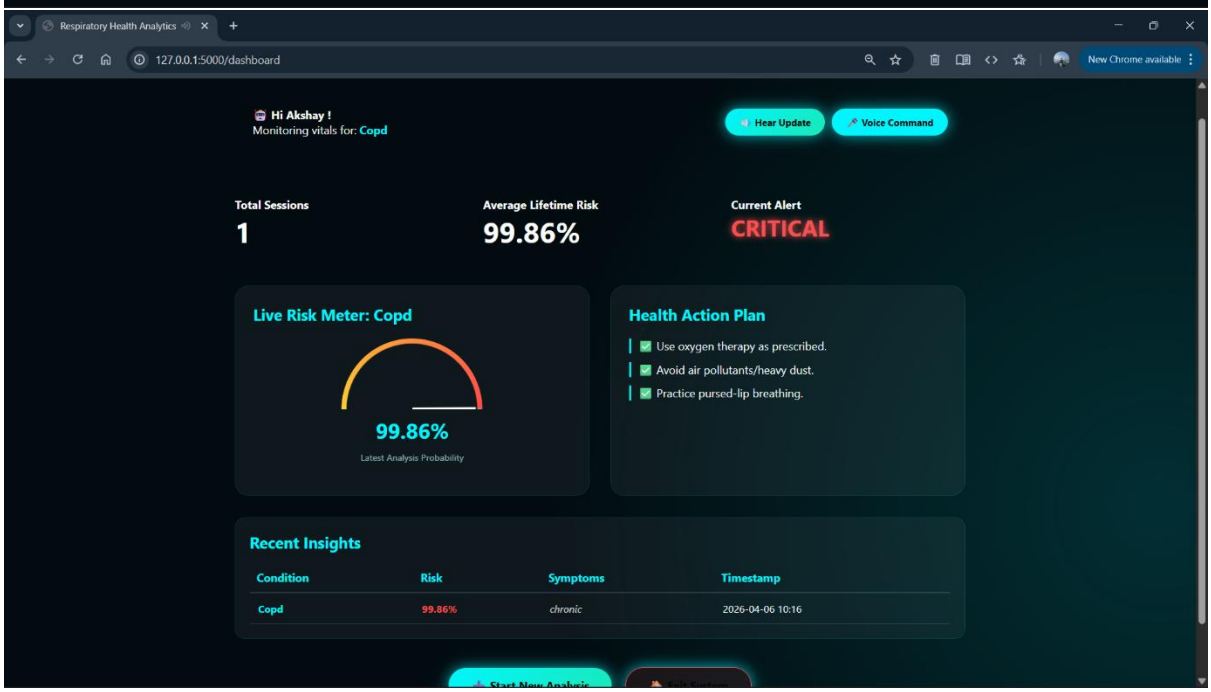
1. **Input Module** – Takes user input (audio file or parameters)
2. **Processing Module** – Extracts features and preprocesses data
3. **Prediction Model** – Trained ML/DL model
4. **Output Module** – Displays predicted disease

Images:









Results

The model is capable of predicting multiple respiratory diseases with good accuracy.

Typical evaluation metrics include:

- Accuracy
- Precision
- Recall

- F1-score

Deep learning-based models in similar systems have achieved accuracy around 95%+, showing high effectiveness in classification tasks

Advantages

- Early disease detection
- Non-invasive diagnosis method
- Fast and automated predictions
- Useful for remote healthcare systems

Limitations

- Depends heavily on dataset quality
- May not generalize well to all populations
- Requires proper preprocessing of audio/data

Future Scope

- Integration with mobile applications
- Real-time prediction using IoT devices
- Improved accuracy using larger datasets
- Integration with hospital systems

Conclusion

- This project demonstrates how machine learning and deep learning can be effectively used for predicting respiratory diseases. By analyzing respiratory data, the system provides accurate and quick predictions, which can assist doctors and healthcare providers in early diagnosis and treatment planning.
- The project highlights the potential of AI in the medical field and opens pathways for further research and development.
